

Problem Statement

Starting a new business in rural or urban areas is challenging because entrepreneurs often lack knowledge about market demand, competition, customer requirements, business feasibility, and suitable shop locations. Businesses such as grocery stores, electronics shops, furniture stores, clinics, supermarkets, cake shops, food stalls, fast-food shops, mechanic shops, juice shops, and meat shops may already exist in a selected area. Opening a similar business without proper analysis can lead to financial loss, market saturation, and low customer reach.

The problem is to develop an AI-based Smart Business Analysis and Recommendation System that helps users identify the most suitable business to establish in rural or urban areas. The system should analyze location-based factors and existing business conditions to determine whether opening a selected business would be feasible, profitable, and sustainable.

Since real-world sales and turnover data are private and difficult to obtain, the proposed system will estimate business feasibility using publicly available location intelligence and market-related factors instead of exact financial records.

The system should evaluate multiple parameters such as:

- Availability of similar shops
- Competition level and market saturation
- Nearby businesses and commercial facilities
- Population density and customer demand
- Road connectivity and transportation
- Parking and nearby public services
- Urban and rural market differences
- Distance from major roads and crowded locations
- Business diversity and customer attraction points
- Future growth opportunities
- Map-based business location analysis

The proposed system should use Artificial Intelligence and Machine Learning techniques to analyze these factors and predict the business viability or success probability for a selected business and location. Based on the analysis, the system should generate a feasibility score or confidence percentage indicating the likelihood of business success.

If the predicted feasibility of the selected business is low, the system should recommend alternative business types with better market opportunities and lower competition. It should also provide location-based recommendations using map and address analysis.

If the selected location is not suitable, the system should automatically recommend better nearby locations with vacant or empty shops, exact address, nearby landmarks, accessibility, competition level, and predicted feasibility score.

The proposed solution aims to support entrepreneurs and small business owners in making data-driven decisions, reducing investment risks, improving business sustainability, and promoting balanced economic growth in rural and urban communities.
